Abstract
Framed in a cognitive approach to task-supported L2 vocabulary learning, the present study used a pedagogical approach to investigate the relative effectiveness of tasks with different involvement loads on the vocabulary knowledge of Iranian EFL learners. The goal was to investigate the way that the construct of involvement load is related to the Input Hypothesis (Krashen, 1985) and the Output Hypothesis (Swain, 1996) to see whether the involvement load or input/output-orientation of tasks is the determining factor in task effectiveness. The participants were 127 university students from four General English classes at the Islamic Azad University, Mobarakeh Branch, who were assigned to four instructional groups. Contrary to the predictions of the Involvement Load Hypothesis (Laufer & Hulstijn, 2001), the results of the study indicated that involvement load is not the only determining factor in task effectiveness, but input/output-orientation of tasks is also a decisive parameter in task effectiveness. While Laufer and Hulstijn’s proposal is the first valuable step towards building a theory of vocabulary learning, the results of the study indicated that involvement index may well not function independently of the task type, i.e., input or output orientation of a word-focused task.

Keywords: EFL, involvement load, input-oriented tasks, output-oriented tasks, vocabulary learning, and Word-focused tasks

1. Introduction

Language learning is probably the most complex type of learning which human beings need to accomplish. Within this complex task, vocabulary, as one of the important components of language knowledge, seems to be of critical importance to both native and non-native speakers of a language. Whereas the number of syntactic patterns that language learners have to learn is finite, vocabulary is an unending task which continues to be learned throughout one’s lifetime. Vocabulary knowledge is considered a prerequisite factor in reading comprehension, a fact that has been recognized in the literature available so far (e.g., Decarrico, 2001; Garcia, 1991; Hazenberg & Hulstijn, 1996; Laufer, 1992; Nation, 1993; Paribakht & Wesche, 1997; Wesche & Paribakht, 1998). Research has shown that lexical errors impede communication more seriously than grammatical ones (Ellis, 1994; Laufer, 1998).

Most research in instructed Second Language Acquisition (SLA) is conducted under the assumption that some interventions are better than others. While many researchers have tended to agree that the vast majority of vocabulary is learned indirectly through reading and listening (e.g., Nagy, Herman, & Anderson, 1985), others (e.g., Laufer, 2005; Nation, 2001) indicate that direct learning tasks, such as word pairs, are effective methods of quickly acquiring vocabularies of a language. Laufer (2002, cited in Laufer, 2005), who has surveyed a large body of evidence, reports that word-focused tasks are effective in improving the vocabulary knowledge of language learners. She believes that it is necessary to see whether word-focused tasks can be classified in terms of their effectiveness in vocabulary learning or not. Language teachers and learners would like to know the ways that instructional programs might foster the acquisition of new words. Of primary concern to researchers and language teachers in the field of L2 vocabulary learning is to identify those tasks that provide the best opportunity for learners to notice and elaborate on new words.

Much of the current research on vocabulary acquisition is implicitly or explicitly based on a cognitive processing view of learning. Of all that
has been done in this field, the Involvement Load Hypothesis (ILH) (Laufer & Hulstijn, 2001) with the basic contention that retention of unfamiliar words is generally conditional upon the degree of involvement in processing these words draws the researchers’ attention. Involvement is operationalized by tasks designed to vary in the degree of need, search, and evaluation. The need component is “the motivational, non-cognitive dimension of involvement” (Laufer & Hulstijn, 2001, p. 14) which can be in moderate and strong degrees. They interpret this notion based on a drive to comply with the task requirements, whereby the task requirements can be either externally or internally imposed. According to them, “need is moderate when it is imposed by an external agent” (p. 14). An example is the need to use a word in a sentence that the teacher has asked for. Need is strong when it is intrinsically motivated, that is, self-imposed by the learner. An example is the decision to look up a word in an L1-L2 dictionary when writing a composition.

Search and evaluation are the two cognitive components of involvement, contingent upon allocating attention to form-meaning relationship (Schmidt, 1990). Search is the attempt to find the meaning of an unknown L2 word by consulting a dictionary or another authority. According to Laufer and Hulstijn (2001), the evaluation component "entails a comparison of a given word with other words, a specific meaning of a word with its other meanings, or comparing the word with other words in order to assess whether a word does or does not fit its context" (p. 14). The kind of evaluation that entails recognizing differences between words (as in a fill-in task with words provided), or differences between several senses of a word in a given context, is referred to as moderate. Evaluation that requires a decision such as how additional words will combine with the new word in a sentence or context is referred to as strong evaluation (Laufer & Hulstijn, 2001).

Each of the above three factors can be absent or present when processing a word in a natural or artificially designed task. The combination of factors with their degrees of prominence constitutes involvement load. The basic proposition of the ILH is that retention of
unfamiliar words is conditional, in general, upon the degree of involvement in processing the unknown words. In other words, it is conditional upon who has set the task and whether it has to be compared or combined with other words. The greater the involvement load, the better the retention.

One of the major areas of interest is the way that the construct of involvement load is related to the Input Hypothesis (Krashen, 1985) and the Output Hypothesis (Swain, 1996). According to Laufer and Hulstijn (2001), the hypothesis does not predict that any output task will lead to better results than any input task. It predicts that higher involvement in a word induced by the task will result in better retention regardless of whether it is an input or an output task. The present study will test this contention. Accordingly, a particularly interesting comparison would involve conditions where the input and output tasks have identical involvement loads. In other words, if involvement load is the determining factor in task effectiveness, irrespective of whether the task is input oriented or output oriented, the two conditions should yield similar retention results.

Following the ILH proposal, many investigations have tried to examine the accuracy of the claim made by Laufer and Hulstijn (2001). Some studies (Fuente, 2006; Hulstijn & Laufer, 2001; Joe, 1995; Keating, 2008) support the claim that tasks with higher involvement loads generally lead to greater gains in short-term and, in some cases, long-term word retention. However, contrary to the predictions of the ILH, Folse (2006) and Kim (2008) found that word-focused tasks with higher involvement loads were as effective as those with lower involvement loads.

As mentioned earlier, studies measuring the relative effectiveness of word-focused tasks with different involvement loads on learners’ vocabulary knowledge have produced conflicting findings. Given the mixed results, it seems necessary to conduct more studies before rushing to support the ILH claims. This motivated the researchers to set out the present study with the intent to determine if the ILH could be generalized
to other EFL contexts, in this case Iran. The main goal of the study was to investigate the effect of tasks with different involvement loads on the vocabulary knowledge of EFL university students. Furthermore, in this study an attempt has been made to relate the construct of involvement load to the Input and Output Hypotheses. The goal was to make a comparison between input and output-oriented tasks with identical involvement loads to see which one plays a more determining role in task effectiveness.

2. Method

2.1 Participants
Primarily, a group of 159 EFL students, who were all Persian native speakers, from four intact university-level classes at the Islamic Azad University, Mobarakeh Branch, participated in this study. They were B.A. and B.S. students who had enrolled in General English course as a requirement of the university curriculum. As the participants were assigned to classes by the university registration office, it was practically impossible to disrupt the regular schedules. Thus, in order to reduce the effects of extraneous variables and selection bias, the four intact classes were randomly assigned to four treatment groups.

Out of the original pool, only the data from 127 students entered into final data analyses. This was due to the elimination of 32 subjects who did not meet the established criteria of the study. Three main considerations were taken into account to select the data for the final analyses. The first criterion was the language proficiency level of the participants measured by Preliminary English Test (PET) (2004). The second criterion was the participants’ attendance in all sessions. The third criterion was the lack of exposure to the target words outside the class during the treatment period. This left a group of 127 participants, both male and female, in four study groups. The age of the participants ranged from 18 to 27. In this study neither gender nor age was a variable.
2.2 Materials
The materials used in this study were four word-focused tasks (two input-based and two output-based) with different involvement loads based on the ones used in the related literature (Hulstijn & Laufer, 2001; Laufer, 2005; Laufer & Hulstijn, 2001; Webb, 2002), and two vocabulary tests for measuring the receptive and productive vocabulary knowledge of meaning.

2.2.1 Word-focused tasks
The participants assigned to Task 1 (Group 1) were provided with sentences containing the target words. The target words were highlighted in bold print to help the participants notice the words, and were glossed in the L1 (Persian) in the margin of the sentences. Each word had more than a single meaning. The task induced moderate need (1) because the participants required the meaning of the target word for understanding the sentence, no search (0) as the participants did not consult a dictionary or other sources to find the meaning of the target word, and moderate evaluation (1) since it required the participants to recognize differences between several senses of a word and choose the one that best fitted the context. So, the Involvement Load Index (ILI) for this task was 2 (1+0+1).

The participants assigned to Task 2 (Group 2) were provided with the same sentences and the same target words as participants who received Task 1. The target words were highlighted in bold print to be noticed, and the participants’ task was to look up the target words in a dictionary. To control the variable, and use the same dictionaries, the participants took part in computer-laboratory classes and used the same software dictionary, Babylon. The tasks induced moderate need (1), moderate search (1), since the meaning of the word was looked up, and moderate evaluation, so the ILI for this task was 3 (1+1+1).

The participants assigned to Task 3 (Group 3) were given the same sentences and the same target words. For this group, however, the bold-faced target words were deleted from the sentences and replaced with
blank spaces. The target words, along with some additional words not present in the original sentences, were printed in alphabetical order as a list on a separate page with their L1 translations. The task required the participants to read the sentences and fill in the gaps with target words from the list. In terms of involvement load, the task induced moderate need (1), no search (0), and moderate evaluation (1). Its ILI was 2 (1+0+1).

The participants assigned to Task 4 (Group 4) were given strings of words including the target word and were asked to rearrange them into meaningful and grammatically correct sentences. In terms of involvement load, this task induced moderate need (1), no search (0), and evaluation was strong (2) because it required the participants to decide on how the additional words were combined with the target word in a sentence. So, the ILI was 3(1+0+2).

2.2.2 Test of receptive and productive knowledge of meaning
In this study, the receptive knowledge of meaning was measured using a receptive translation test, in which a list of 33 target words was given to the participants with a blank beside each word. The participants’ task was to write the Persian equivalent of the target words to score a correct response. Nation (2001) suggests that having learners write the translation of words may be a more effective method of measuring meaning than multiple-choice tests. Furthermore, translation tests reduced the time needed for students to complete the test.

The productive knowledge of meaning was measured using a sentence making test. In this test, the participants were asked to write the target words in meaningful sentences. A score of 1 was allocated to each meaningful sentence using the target word. As Nation (2001) states, sentence making format ensures that participants will demonstrate semantic knowledge of the word. Furthermore, the test format was quick and clear to the elementary learners in comparison to some other test formats such as essay writing.
2.3 Procedure
The general procedures employed in this study can be divided into two main phases: developing and piloting the materials, and conducting the main phase of the study.

2.3.1 Phase one: developing and piloting the materials
Primarily, a group of 63 low frequency words from 3,000 Word Frequency List (Nation, 2001) was selected for the study. The target words were unfamiliar to the participants as they were checked in the pretest. Factors considered when establishing the number of the target words were subject fatigue, time needed to complete the tasks and tests, and the results of item characteristics in the pilot study. Many of the words were deleted from the list because of unacceptable item characteristics Indices. It left a group of 33 words as the target words in the study. The words included Nouns (11 words), Verbs (11 words) and Adjectives (11 words). The justification was that nouns, verbs, and adjectives were the most common parts of speech as grammatical functions of the words. Only one sense of the target words appeared in the sentences. The same target words were used in the treatment tasks and the assessment.

The target words were presented in short sentences. The sentences were selected from Oxford Learner’s Dictionary and British National Corpus. Three factors were considered when selecting the sentences: the number of words, the frequency of the words, and the ease in comprehending the sentences. The average length of the sentences for the target words was 10.8 words. Sentences that contained words unknown to the subjects in the pilot study were eliminated.

The tasks were developed by the researcher after reviewing the relevant literature and were based on the tasks used in the published research. Before the commencement of the main study, the tasks were piloted on a sample of 110 students who had enrolled in General English courses in the first semester. The sample was different from the main participants. All teaching procedures were trialed at this stage. The
piloting was done to determine the time required for doing the tasks in the main study, to check the practicality of using the tasks in the class, and to determine the possible practical problems in implementing the tasks. Time on task was different for all four tasks. Tasks 1, 2, 3, 4 took about 35-40, 60-70, 40-45, and 70-80 minutes, respectively. Task 4 was the most demanding and time consuming. It is often argued that time on task should be kept identical in research on task effectiveness. Yet, in this study time on task was regarded as an inherent property of the task, not as a separate variable.

The vocabulary tests used in this study were also developed by the researcher based on the measurements available in the relevant literature (e.g., Fuente, 2006; Hulstijn & Laufer, 2001; Keating, 2008; Webb, 2002). The items aimed at assessing the participants’ receptive and productive knowledge of meaning. The number of items was far more than what was really needed in the main study. The goal of piloting the test was to examine item characteristics and test the characteristics. First, Item Facility (IF) of the test items was calculated. The acceptable index for IF was between 0.33 and 0.67. Thus, the items with higher or lower than these indices were rejected. Second, item discrimination (ID) of the items was calculated. To do so, a High-Group (HG) and Low-Group (LG) classification was established to calculate the ID. According to Henning (1987), the optimal size of each group is 28% of the total sample. Then, the performance of HG students was compared with that of the LG students. In this method, a discriminability index of 67 is considered as the lowest acceptable discriminability.

The results of item characteristics analyses (IF and ID) left 36 items for the main study. To ensure the content validity of the test, the content of the test and the content of the tasks were examined carefully and critically by expert judges. The experts were the research supervisor and three university faculty members who had reviewed the word-focused tasks. As a result of the panel views, several items were either discarded or modified. Furthermore, an internal-consistency method (Cronbach’s Alpha) was used to calculate the reliability of the test. The
reliability was estimated from the test scores in the two posttests. The underlying reason was that there was very little variability in the pretest scores which would decrease the reliability indices. The reliability measures for the immediate posttest (.79) and the delayed posttest (.76) were high enough to confirm the reliability of the test. As Jafarpour (1992) states, for teacher-made tests, a reliability of .60 and above is adequate.

2.3.2 Phase two: Main study
The main study was conducted in the semester following the pilot study. The primary objective of General English courses is to develop the learners’ reading comprehension abilities. The students should be taught a reading book recommended by the English Department of the University. Each chapter in the book includes a list of new words, a passage for comprehension, some text-related comprehension questions, and grammar.

In this study, training the groups and administration of the measurements were performed by the researcher, who was also the instructor, to control for teacher variable and ensure the elimination of possible differences in the implementation of the instructional tasks by different teachers. This could help avoid the possible threats to the internal validity of the study. The subsequent steps taken in the main phase of the study were as follows:

First, the PET test was administered in the second week of the semester in order to ensure the homogeneity of the four groups in terms of their language proficiency before the commencement of the study. To make sure that the participants were homogenous in terms of their language proficiency level, the reading and writing sections of the test were administered to the original pool before the commencement of the study (the listening and speaking sections of the test were not administered due to practical limitations). The mean (M= 21.35) and standard deviation (SD = 7.14) of the scores on the PET test were used as the criteria for choosing the participants. The participants who scored
higher or lower than one standard deviation plus/minus the mean of the sample (M +/- SD) were considered as high and low proficient, respectively, and were excluded from the final data analyses. The data belonging to those participants who scored one standard deviation above or below the mean were included in the final data analyses. The total scores of the remaining subjects were then entered into one-way ANOVA with the alpha set at p < .05. The results revealed no significant difference across the groups as far as language proficiency level was concerned: F (3, 136) = 0.961, p = .394 > .05.

Second, the pretest was administered in the third week of the semester. The first purpose of administering the pretests was to examine the likelihood of the target-word familiarity among the participants before the treatment commencement. The goal was to ascertain the knowledge of the target words and to select a group of target words unknown to all participants. Three participants were excluded after the test; all other participants showed no previous knowledge of the target words. The second purpose was to address the research questions concerning the possible effectiveness or superiority of one word-focused task over the other in developing the participant’s receptive vocabulary knowledge of meaning.

Third, since the unfamiliarity of the participants with the word-focused tasks could affect the tasks, the groups were first given the opportunity to get familiar with the tasks and practice the kind of activities they were supposed to receive. For three weeks, they practiced the list of the new words of their regular course book in the way they were supposed to practice the target words of the study. It was effective especially for the second (looking up the words in a software dictionary) and the fourth (sentence making) groups.

Fourth, the instructional treatments in the groups started in the seventh week and within a three-week interval of the pretest administration. All instruction and assessment took place in the participants’ regular class time by the instructor. All participants were informed that they were participating in a study. They were told that the
The Journal of Teaching Language Skills / 4(2), Summer 2012, Ser. 67/4

The research involved the relationship between vocabulary learning tasks and their effects on vocabulary learning. According to Hulstijn (2003), methodologically speaking, test announcement is part of intentional vocabulary learning. The participants took all tasks and posttests within regular classrooms during regular class time. On the treatment day, the participants in each of the four classes were given one of the experimental tasks which should be completed by individual learners. As word-focused tasks will be of little use without providing the students with the feedback on the accuracy of their choices or activities, the instructor provided some additional information. Whenever needed, the participants could enjoy peer feedback while completing the tasks. Cognizant of the fact that time on task would vary among the treatment groups, the researcher asked the participants to turn their worksheets face down when completed and wait for others to finish. In all the groups, the worksheets were collected after the completion of the tasks.

Fifth, to assess the initial recall of the target words, the IP was administered to the groups after the completion of the tasks. The same test in pretest was used as posttest.

Sixth, the DP was administered to the groups to examine whether benefits of each of word-focused tasks would last over time or not. The DP was administered after a one-month interval. During the interval, the participants continued working on the reading comprehension book with no contact with the target words.

An attempt was made to equalize the administration procedures in all groups to increase the reliability and the internal validity of the measures (Arey, Jacobs, & Razavieh, 1996). In all test administrations, the instructor was present for clarifying the ambiguities for the examinees. After the required data were collected, they were subjected to different quantitative analyses.

3. Results
In order to investigate whether each individual study group (Groups 1, 2, 3, and 4) improved in the receptive and productive knowledge of
meaning from the pretest to the IP and the DP, the within group changes over time were analyzed both descriptively and inferentially. It was shown that, from the means and standard deviations of the groups’ raw scores on the receptive and productive tests of meaning over the three test administrations (Tables 1 and 2), all the study groups improved from the pretest to the IP. Although there was a decline on the DP for all the study groups, none of the groups returned to the same level of performance as before the task-oriented instruction, showing the effectiveness of the word-focused tasks on the participants’ receptive and productive vocabulary knowledge of meaning over time.

Figures 1 and 2 graphically show the difference between the participants’ receptive and productive knowledge of meaning in different study groups. As shown, there is an improvement in the receptive and
productive vocabulary knowledge of meaning from the pretest to the IP in all the study groups. However, there is a decline on the DP for all the study groups.

Figure 1. Groups’ performance on the receptive Test of meaning over time

Figure 2. Groups’ performance on the productive test of meaning over time
Although the results of within-group comparisons indicated that the word-focused tasks were all effective in improving the receptive and productive vocabulary knowledge of meaning in each single group, they could not show if the results were statistically equal for all the groups or not. Thus, a series of one-way repeated ANOVAs were conducted to examine simple main effects of word-focused tasks on the IP. The results of ANOVA conducted on the receptive and productive meaning scores of the groups on the IP revealed a significant difference in how the study groups performed on the test of receptive meaning ($F(3,123) = 2.695, p = 004 < .05$) and the test of productive meaning ($F(3,123) = 368$, $p = .00 < .05$).

The results of ANOVA (Tables 3 and 4) indicated that word-focused tasks did not produce equal results in the groups’ receptive and productive vocabulary knowledge of meaning. In order to specifically locate the differences among the study groups, LSD, as an adjustment for pair-wise comparisons, was used to detect the precise location of the differences. The results indicated that there were significant differences between Groups 1 and 4, and Groups 2 and 4. In other words, Group 4 outperformed Groups 1 and 2 in the receptive measure of meaning. The results indicated no significant differences between Groups 1 and 2, Groups 1 and 3, Groups 2 and 3, and Groups 3 and 4. The results of post
hoc analyses are summarized as follows: Group 4 > Group 1=Group 2=Group 3; Group 3=Group 4 (with > meaning better than, and = indicating no significant differences).

Furthermore, post hot tests were run on the results of productive measures of meaning to specifically detect the precise location of differences among the study groups. The results indicated that there were no significant differences between Groups 1 and 2, on the one hand, and between Groups 1 and 3 as well as Groups 3 and 2, on the other hand. However, significant differences were found between Groups 4 and 1, Groups 4 and 2, and Groups 4 and 3. In other words, Group 4 significantly outperformed the other three groups in the productive measures of meaning. The performance of the participants on the IP can be summarized as follows: Group 4 > Group 1 = Group 1 = Group 2 = Group 3.

To see whether there were any significant differences among the study groups on the DP, a series of one-way repeated ANOVAs were conducted to examine simple main effects of word-focused tasks on the DP. The results of ANOVA conducted on the meaning scores of the study groups on the DP revealed a significant difference in how the study groups performed on the test of receptive meaning ($F(3, 123)= 2.592, p= .005<.05$) and the test of productive meaning ($F (3, 123) = 3.822, p=.012<.05$).

The Relative Effectiveness of Input and Output-oriented Tasks with Different …

The results of ANOVA (Tables 5 and 6) indicated that the word-focused tasks did not have the same effect on the study groups’ receptive and productive vocabulary knowledge on the DP. In order to specifically locate the differences among the study groups’ receptive vocabulary knowledge on the DP, LSD tests were run on the data. The results of pair-wise comparison indicated that there were no significant differences between Groups 1 and 2, Groups 1 and 3, as well as Groups 2 and 3, and Groups 3 and 4. However, a significant difference was found between Groups 1 and 4 as well as Groups 2 and 4. The results can be summarized as follows: Group 4>Group 1=Group 2; Group 4=Group 3; Group 3=Group 1=Group 2.

To detect the precise location of differences among the study groups’ productive vocabulary knowledge of meaning, a post hoc test was run on the data. The results of pair-wise comparisons indicated that there were no significant differences between Groups 1 and 2, Groups 1 and 3, Groups 2 and 3, and Groups 3 and 4. However, significant differences were found between Groups 4 and 1, and Groups 4 and 2. The results of post hoc analyses are summarized as follows: Group 4>Group 1=Group 2; Group 4=Group 3; Group 3=Group 1=Group 2.

4. Discussion

The first finding of the study was related to the relative effectiveness of input/output-oriented word-focused tasks with different involvement loads on learners’ receptive and productive vocabulary knowledge of meaning. The findings of between-group comparisons revealed that the study groups performed differently both on the IP and DP, reflecting that the gains were not equal for all the study groups. The results of the study indicated that the participants who completed Task 4 (sentence-making) performed remarkably better than the participants who completed Tasks 1, 2, and 3, on both the IP and DP. In other words, a significant advantage was found for Task 4 over the other word-focused tasks. This finding is in accordance with the results obtained by Ellis and He (1999),

The results of this study indicated that sentence production, as an output-oriented task with an involvement load of 3, contributed to extensive gains in learners’ vocabulary knowledge. The first plausible explanation for the stronger effect of output-oriented tasks is learners' attention to form. This explanation is in line with Toth's (2006) argument indicating that the learners' internal language processes engaged during the output-oriented tasks might have yielded greater benefits for learning than those of input-oriented tasks. As Izumi (2002) states, output-oriented tasks facilitate L2 development by forcing learners to reflect on the L2 forms. The second explanation which might account for the superiority of output-oriented tasks to input-oriented tasks is task demand. Output-oriented tasks involve both processing input and production, while input-oriented tasks involve only input processing. Toth (2006) argues that in output-oriented tasks learners receiving instruction have to respond by encoding their own meaning, but in input-oriented tasks learners have to respond to input by signaling its meaning. The last possible explanation for the superiority of sentence-making task is that this task, as an effective word-focused task, has been used in the process of learning L1 (Persian) words in elementary schools. Most Iranian EFL learners have had the experience of using sentence-making task in their instructional programs in the process of learning their first language. According to Ellis (2003), familiarity with the task is one of the factors that may promote learning more effectively. Sentence-making provides opportunities for more elaborate processing of the target words in the process of language learning.

The results of the IP and DP revealed that in the receptive test of meaning the participants who completed Task 4 (output-oriented task with an involvement load of 3) outperformed those who completed Task 1 (input-oriented task with an involvement load of 2) and Task 2 (input-oriented task with an involvement load of 3). The significance of the difference between Tasks 1 and 4 partially supports the ILH in that both
the involvement load and input/output orientation of tasks might have significant roles in task effectiveness. However, the significant difference between Tasks 2 and 4, and lack of significant difference between Tasks 1 and 2, and Tasks 3 and 4 indicated the significant role of input/output orientation of tasks.

The findings indicated that, in addition to the involvement load of tasks, input or output orientation of a task is a determining factor in task effectiveness. If involvement load were the only determining factor in task effectiveness, irrespective of whether the task was input or output-based, the two conditions would yield similar retention results. However, the lack of significant difference between Groups 1 and 2 and the outperformance of Group 4 in comparison with Group 2 (both with an involvement load of 3) revealed that involvement load was not the only determining factor in task effectiveness. Similar to Folse's (2006) findings, the results of the study were in contrast with the predictions of the ILH. This revealed that in addition to the involvement load, other factors should be considered in determining task effectiveness.

Unlike previous studies (Fuente, 2006; Hulstijn & Laufer, 2001; Keating, 2008) which fully support the hypothesis, the results of this study partially support the ILH. Based on the hypothesis, it was anticipated that Task 2 (looking up new words in a dictionary) with an involvement load of 3 would be as effective as Task 4 (sentence-making) with an involvement load of 3. However, the results indicated that it was the other way round, in that Task 4 resulted in higher gains compared to Task 2. One possible explanation for this is that numerical values to the motivational and cognitive elements of the ILH, which in turn yield the involvement index, may not carry the same weight or may have been roughly quantified. In this hypothesis, the amount of the involvement load has been conceived as the sum of the pluses (of need, search, and evaluation). For example, a task consisting of + need, + search, and - evaluation has the same involvement load as a task consisting of + need, - search, and + evaluation. Yet, all the three factors may not be equally important for vocabulary learning. This explanation is
very much in line with Kim's (2008) argument. As Kim states, "it is possible that all the three components might not be equal in contributing to vocabulary learning" (p. 313). Along the same line, it might be claimed from the results of this study that each individual component may have a higher or lower variable involvement load. Furthermore, the findings are in accordance with what has already been achieved by Folse (2006). Contrary to the predictions of the hypothesis, he found that using tasks with strong evaluation was as effective as tasks with moderate evaluation.

The findings of this study also provided insights for the way that the construct of ILH is related to the Input and Output Hypotheses. The superiority of Task 4 (sentence making) as an output-oriented task may seem to support Swain's Output Hypothesis (1996), given that the sentence-making task requires the learners to stretch their linguistic resources and notice language forms and elaborate on them. The findings of the study supports Swain’s (1993) claim that understanding new forms is not enough and that learners must also be given the chances to use them. Output production induces learners to reflect upon language form and this makes acquisition more likely to occur. Swain’s (1996) theoretical standpoint is that, without pushed output, learners engage in input comprehension, which does not guarantee future processing of linguistic form that leads to acquisition. One explanation is that output production allows for deeper processing of the L2 words by helping learners to establish more productive meaning-form connections through multiple opportunities for output production of target words. According to Swain (1998), one of the major functions of output is promoting the learners’ noticing and enabling them to notice a gap in their existing knowledge brought to their attention by external or internal feedback. The findings of the study are in line with Gass and Selinker’s (2008) argument indicating that input alone is not sufficient for acquisition and that output production has an effective role in language learning. The results of the current study indicate that the involvement load may well not function independently of the task type, that is, the input or output
orientation of the tasks. In other words, the processing load brought to bear by task type may well affect word retention, a point needing further empirical studies.

Regarding the durability of the word-focused tasks, similar to the findings of Fuente (2006), Keating (2008), and Webb (2005), the results indicated that the improvement for the groups remained significant between the pretest and the DP; however, the groups’ mean scores showed some decrease on the DP as compared with their mean scores on the IP. One possible explanation that is very much in line with Hulstijn and Laufer's (2001, p. 274, footnote 20) argument is that “one expects a decline in knowledge over time in the absence of rehearsal or additional exposure to the target words”. The participants in this study were not exposed to the target words between testing intervals. Thus, it is not surprising that there would be a decline in knowledge for the task that initially showed the greatest gains.

5. Conclusion
The main goal of the study was to make a comparison between input and output-oriented tasks with identical involvement loads to see which one plays a more determining role in task effectiveness. It can be concluded that the output-oriented task with high involvement loads produced more effective and more durable effects. As Fuente (2006) states, the output production tasks promote attention to form and meaning and help the learners make form-meaning connections. He concludes that word-focused tasks seem to be sound pedagogical tools for the acquisition of L2 vocabulary items from a task-supported language teaching approach. The most significant conclusion drawn from the present study was that, unlike previous studies which rather unambiguously endorsed the ILH, involvement load is not the only determining factor in tasks effectiveness. Rather, in addition to the involvement load of word-focused tasks, the input/output-orientation of tasks is also important in determining the effectiveness of a word-focused task. It can be concluded that although Laufer and Hulstijn’s (2001) proposal is conceived of as an
attempt to stimulate researchers as well as practitioners to operationalize traditional general labels such as noticing, attention, and motivation into task-specific components, it has a long way to go before it achieves its full potential. The findings indicated that there may be more than three determining factors in vocabulary learning. It can be concluded that tasks type, i.e., input or output orientation of a word-focused task, may also be a determining factor. In other words, the involvement index may well not function independently of the task type for vocabulary instruction.

The conclusion that output-oriented tasks were more effective in improving the vocabulary knowledge of learners in this study adds further support to the widely-acknowledged roles of output and the functions that Swain (1993, 2000) has listed for the output. It seems that involvement load is not the only determining factor in every language and for all learners and, consequently, its beneficial effects should not be overgeneralized. It is worth mentioning that the greater role of output-oriented tasks in this study does not obviate the role of involvement load in task effectiveness.

The findings of this study might provide a useful tool for language instructors and educators in their selection of effective word-focused tasks. Since vocabulary is considered as one of the important components of reading comprehension ability of learners, it might be necessary for teachers to include some word-focused tasks in General English courses where the primary emphasis is placed on the knowledge of the reading comprehension. Furthermore, the finding that output-oriented tasks with high involvement loads were more effective for vocabulary learning than input-oriented ones with the same involvement load is an encouraging finding for instructors and researchers who are eager to know in which ways instructional programs might foster the acquisition of target words. Although input-based tasks seem easier and less time-consuming than output-based tasks, given the superiority of sentence-making as an output-based task with high involvement load in this study, it seems plausible to use output-oriented tasks with high involvement loads in General English classes. It does not seem reasonable to completely put
aside output-based tasks only because they might be time consuming or might put too much work on learners’ shoulders. The inclusion of such tasks might be crucial to effective vocabulary knowledge.

Similarly, the conclusion that output-oriented tasks with high involvement loads were more effective for vocabulary learning than input-oriented ones with the same involvement load is an encouraging finding for autonomous learners. In other words, autonomous learners can be informed about the effectiveness of different word-focused tasks so they can make strategic decisions concerning the selection of the most appropriate tasks for improving their vocabulary knowledge.

Furthermore, the results of the current study might provide useful insights for the developers of instructional materials and syllabus designers in their selection of effective word-focused tasks in EFL General English materials. It can hardly be denied that an adequate and sufficient vocabulary knowledge leads to good comprehension. Thus, given the importance of vocabulary in EFL General English classes, any word-focused task that helps learners to develop their vocabulary knowledge would certainly be welcomed.

And finally, this study could possibly lay the groundwork for a great deal of research to touch on the effect of different word-focused tasks on various aspects of vocabulary knowledge. Many other questions may be raised in relation to the findings of this study. It seems necessary to provide more precise definitions of the involvement components or add new components to the three proposed by Laufer and Hulstijn (2001) and provide a theoretical underpinning for each of them.
